Abstract

Computational Cluster organizes and executes time consuming computational tasks. Especially for exact optimization algorithms with $o(2^n)$ time complexity.

The architecture of a system and a communication protocol design should focus on maximizing the effective usage of a resources (i.e. usage of computational power).

1 Glossary

Task manager - divides tasks for *computational nodes* to compute into *partial problems* and composes the final solution from all the *partial solutions*.

Computational node - computes the *partial problems* and sends *partial solutions* for them to the *task manager* through the *communications server*

Communications server - receives and dispatches *problem instances* and *partial solutions* to *task managers* and *computational nodes*.

Computational client - an application connecting to the *communications server* and sending to it the *problem instance* and waiting for the solution.

Problem instance - an identifier of a class of a problems (e.g. Travelling Salesman Problem) together with a specific instance (e.g. graph describing the cities location and routes between them).

Partial problem - part of a problem to be processed by a *computational node*.

Partial solution - the best solution for the *problem instance* found by a single computational node.

Task solver - module used by the *computational client* in order to find a *partial solution* from a *partial problem*

2 Task

The task is to design (till 31 January 2014) and develop (next semester) the architecture and communication protocol for the **Computational Cluster** and all its components.

3 Design requirements

Design documentation is to be prepared by 4 people teams. It must be sent to the teacher via mail in PDF format before the end of the semester. Please note that diagrams must be created with special treatment to be readable on a computer screen. The first page should contain a list of team members.

Required artefacts

1. Requirements Specification:
 - (a) System actors' use case
 - i. Person running a Communications server
 - ii. Person running a Task manager
 - iii. Person running a Computational node
 - iv. Person running a Computational client
 - v. Communications server communicating with task manager, computational node and computational client
 - vi. Task manager connecting and communicating with communications server
 - vii. Computational node connecting and communicating with communications server
 - viii. Computational client connecting and communicating with communications server
2. Complete Design Documentation (Computational Cluster and Task Solver):
 - (a) Input data format specification (if any)
 - (b) Class diagrams - describing structures, modules and architecture of the system
 - (c) Event flow diagrams - describing interaction between
 - (d) State diagrams - describing states of components of Computational Cluster and Task Solver for a given problem
 - (e) Important activity diagrams and/or sequence diagrams - describing overall activities of the server and clients
 - (f) Communication protocol design (suggested: XML Schema + examples of XML documents)

- (g) Additional relevant comments
 - (h) Special system states description (initialization, shut down, failures)
3. Vocabulary (if needed)

4 Normal activity description

Task managers and computational nodes for a given class of problems register to the server. Server asks them about the name(s) of the class of problems that they can manage/solve.

Task manager

- sends names of the class problems to the server
- receives a problem instance to divide among computational nodes
- receives the number of computational nodes
- sends partial problems
- receives the partial solutions
- chooses and sends the final solution

Computational node

- sends names of the class problems to the server
- receives a partial problem to solve
- solves a partial problem
- informs server that computation is ongoing
- sends partial solution to the server

Computational client

- sends problem instance to the server
- receives the final solution

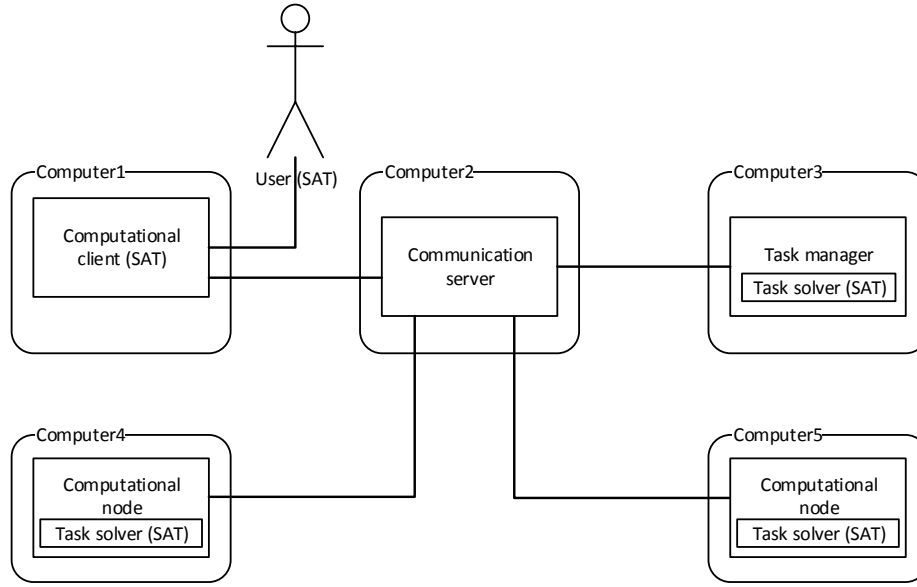

Figure 1: A simple deployment of components

Communications server

- sends problem instance to the task manager
- receives partial problems and sends them to the computational node
- manages states of computational nodes and assigned partial problems (send, computing, communication lost, ...)
- queues and (possibly) resends partial problems in case of computational nodes failures
- receives partial solutions and send them to the task manager
- receives final solution from the task manager and sends them to the computational client

5 Deployment scenarios

Figures 1 and 2 depict a simple and a complex version of deployment of system component over the hardware.

Figure 1 presents a simple configuration with 2 computational nodes, 1 task manager and a single client solving a SAT problem. Figure 2 presents a configuration with two clients, different kinds of computational nodes and many components are deployed on a single machine.

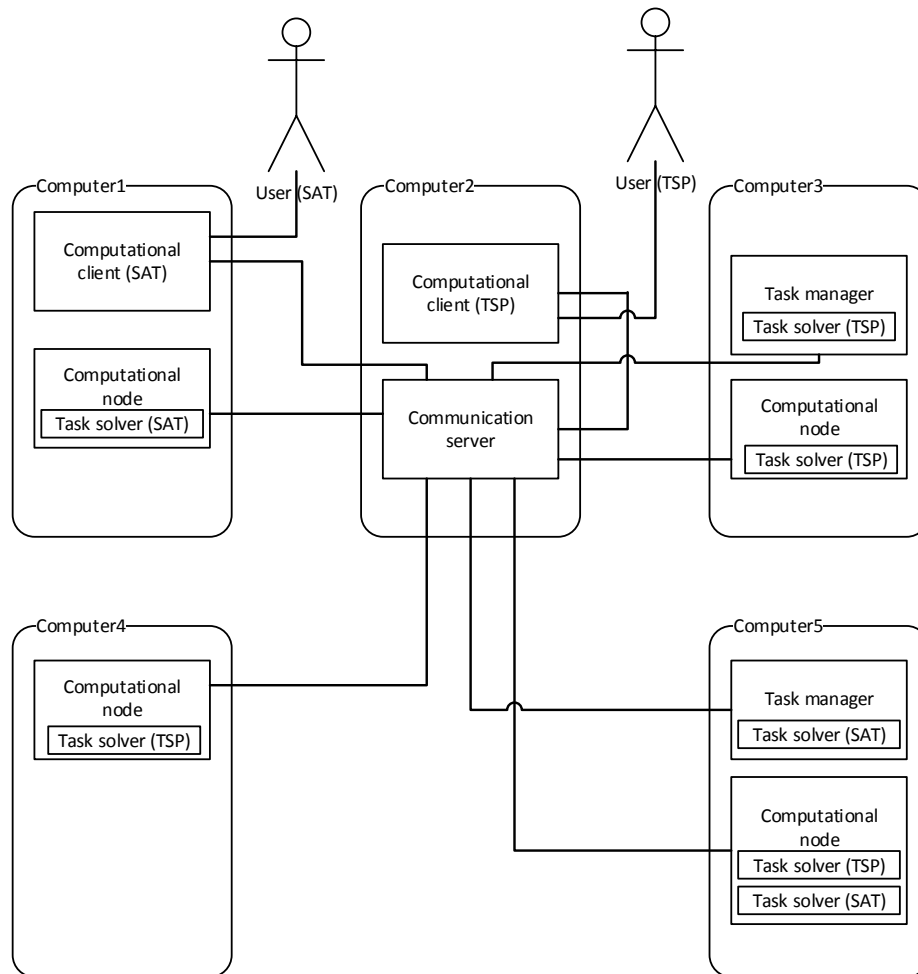

Figure 2: A complex deployment of components

6 An example class of problems

An example class of problems could be a Dynamic Vehicle Routing Problem, a dynamic version of generalization of the Travelling Salesman Problem. The description of the particular type of DVRP, the Vehicle Routing Problem with Dynamic Requests could be found in [1].
